Lecture 3a: Const and References

CS 70: Data Structures and Program Development

Tuesday, February 4, 2019

Learning Targets

- 1. I can use references in my code
- 2. I can visualize references in the CS70 memory model
- 3. I know what the const keyword means
- 4. I can use the const keyword in my programs
- 5. I can track which variables are constant in the memory model

References

Reference Types

Reference Types

```
int a = 10;
int b = a; // b is an int
            // whose value is the value of a
VS.
int a = 10;
int& b = a; // b is a reference to an int
            // that refers to the variable a
```

New Diagram Rules

- When a function is called, allocate space for all local variables
 except references.
- When a reference is initialized, write its name next to its referent.
- When a reference is destroyed, cross out its name (not necessarily the referent's name!).

```
int m = 10; // m is an int whose value is 10
int& n = m; // n is a reference to an int
             // that refers to m
int p = 20; // p is an int whose value is 20
m = 5;
cout << "m = " << m << ", n = " << n << endl;
n = p;
cout << "m = " << m << ", n = " << n << endl;
```

```
int a = 10;
int& b = a;
int& d = b;

d = 20;
cout << "a = " << a << ", b = " << b << endl;</pre>
```

What does this code print?

```
void spotTransplant(Cow donor, Cow recipient) {
    size t donorSpots = donor.getNumSpots();
    size t recipientSpots = recipient.getNumSpots();
    recipient.setNumSpots(donorSpots + recipientSpots);
    donor.setNumSpots(0);
}
int main() {
    Cow buttercup{5, 3};
    Cow flopsy\{3, 13\};
    spotTransplant(flopsy, buttercup);
    cout << "Buttercup: " << buttercup.getNumSpots() << " spots." << endl;</pre>
    cout << "Flopsy: " << flopsy.getNumSpots() << " spots." << endl;</pre>
```

What does this code print?

```
void spotTransplant(Cow& donor, Cow& recipient) {
    size t donorSpots = donor.getNumSpots();
    size t recipientSpots = recipient.getNumSpots();
    recipient.setNumSpots(donorSpots + recipientSpots);
    donor.setNumSpots(0);
}
int main() {
    Cow buttercup{5, 3};
    Cow flopsy\{3, 13\};
    spotTransplant(flopsy, buttercup);
    cout << "Buttercup: " << buttercup.getNumSpots() << " spots." << endl;</pre>
    cout << "Flopsy: " << flopsy.getNumSpots() << " spots." << endl;</pre>
```

New Diagram Rules

- When a function is called, allocate space for all local variables
 except references.
- When a reference is initialized, write its name next to its referent.
- When a reference is destroyed, cross out its name (not necessarily the referent's name!).

New Diagram Rules

- When a function is called, allocate space for all local variables
 except references.
- When a reference is initialized, write its name next to its referent.
- When a reference is destroyed, cross out its name (not necessarily the referent's name!).
- When the referent is in a different stack frame, note that on the right side of the diagram.

Your Turn...

```
void div(int a, int b, int& quo, int& rem) {
    rem = a;
    quo = 0;
    while(rem >= b) {
        rem = rem - b;
        ++quo;
int main() {
    int x = 24;
    int y = 7;
    int quotient;
    int remainder;
    div(x, y, quotient, remainder);
    cout << "x = " << x << ", y = " << y;
    cout << " quotient = " << quotient << ", remainder = " << remainder << endl;</pre>
}
```

Warning: C++ References aren't Java References

A C++ reference is never "null"

A C++ reference cannot be "moved" or "redirected"

Defining Constants

```
const int PENNIES_PER_DOLLAR = 100;
const string WELCOME_MSG = "Greetings!";
const double SQRT2 = sqrt(2);
```

New Diagram Rules

- When a function is called, allocate space for all local variables
 except references.
- When a reference is initialized, write its name next to its referent.
- When a reference is destroyed, cross out its name (not necessarily the referent's name!).

New Diagram Rules

- When a function is called, allocate space for all local variables
 except references.
- When a reference is initialized, write its name next to its referent.
- When a reference is destroyed, cross out its name (not necessarily the referent's name!).
- Draw a padlock on names that are labeled as const (can't use this name to change this value).

const and References

```
int a = 3;
const int& b = a;
++a; //Okay!
++b; //Causes a compiler error!
```

const and References

```
int a = 3;
const int& b = a;
++a; //Okay!
++b; //Causes a compiler error!
const int e = 3;
const int& f = e; //Okay!
```

const and References

```
int a = 3;
const int& b = a;
++a; //Okay!
++b; //Causes a compiler error!
const int e = 3;
const int& f = e; //Okay!
const int c = 3;
int& d = c; //Causes a compiler error!
// (not on worksheet)
```

How many errors in this code?

```
int a = 3;
const int b = a;
int \& c = a;
const int& d = a;
int \& e = b;
++a;
++b;
++c;
++d;
```

Easy way to make the function more efficient?

```
size t getSize(vector<int> v) {
    return v.size();
int main() {
    const vector<int> w(100000);
    cout << getSize(w) << "\n";</pre>
    return 0;
```

Easy way to make the function more efficient?

```
size t getSize(vector<int>& v) {
    return v.size();
int main() {
    const vector<int> w(100000);
    cout << getSize(w) << "\n";</pre>
    return 0;
```

Easy way to make the function more efficient?

```
size t getSize(const vector<int>& v) {
    return v.size();
int main() {
    const vector<int> w(100000);
    cout << getSize(w) << "\n";</pre>
    return 0;
```

Static Const Class Members

- We can declare a member of a class as static const.
- No matter how many objects of the class are created, there is only one copy of the static const member.
- A static const member is shared by all objects of the class.

```
In cow.hpp:
class Cow{
    ...
    static const string TAXONOMIC_FAMILY = "bovidae";
    ...
};
In main.cpp:
cout << Cow::TAXONOMIC_FAMILY << endl;</pre>
```

Makefiles

A helpful tool to automate compiling

Makefile rules

```
target: dependency_1 dependency_2 ...
<tab> commands_to_run
```

Example

Suppose farm.cpp includes cow.hpp. We can write a make rule:

```
farm.o: farm.cpp cow.hpp
    clang++ -o farm.o -c farm.cpp
```

The program make detects if farm.cpp or cow.hpp have changed since the last time farm.o was generated, and then (re)compiles into farm.o if necessary.
